CROSS-REFERENCE TO RELATED APPLICATION

The present application is a continuation in part of USSN 08/813,507, filed March 7, 1997, which derives priority from provisional application 60/032,069, filed December 2, 1996, both of which are incorporated by reference in its entirety for all purposes.

20

BACKGROUND OF THE INVENTION

The genomes of all organisms undergo spontaneous mutation in the course of their continuing evolution generating variant forms of progenitor sequences (Gusella, *Ann. Rev. Biochem.* 55, 831-854 (1986)). The variant form may confer an evolutionary advantage or disadvantage relative to a progenitor form or may be neutral. In some instances, a variant form confers a lethal disadvantage and is not transmitted to subsequent generations of the organism. In other instances, a variant form confers an evolutionary advantage to the species and is eventually incorporated into the DNA of many or most members of the species and effectively becomes the progenitor form. In many instances, both progenitor and variant form(s) survive and co-exist in a species population. The coexistence of multiple forms of a sequence gives rise to polymorphisms.

35

Several different types of polymorphism have been reported. A restriction fragment length polymorphism (RFLP) means a variation in DNA sequence that alters the length of a restriction fragment as described in Botstein et al., *Am. J. Hum. Genet.* 32, 314-331 (1980). The restriction fragment length polymorphism may create or delete a restriction site, thus changing the length of the restriction fragment. RFLPs have been widely used in human and animal genetic analyses (see WO 90/13668; W090/11369; Donis-Keller, *Cell* 51, 319-337 (1987); Lander et al., *Genetics* 121, 85-99 (1989)). When a heritable trait can be linked to a particular RFLP, the presence of the RFLP in an individual can be used to predict the likelihood that the animal will also exhibit the trait.

Other polymorphisms take the form of short tandem repeats (STRs) that include tandem di-, tri- and tetra-nucleotide repeated motifs. These tandem repeats are also referred to as variable number tandem repeat (VNTR) polymorphisms. VNTRs have been used in identity and paternity analysis (US 5,075,217; Armour et al., *FEBS Lett.* 307, 113-115 (1992); Horn et al., W0 91/14003; Jeffreys, EP 370,719), and in a large number of genetic mapping studies.

Other polymorphisms take the form of single nucleotide variations between individuals of the same species. Such polymorphisms are far more frequent than RFLPs, STRs and VNTRs. Some single nucleotide polymorphisms occur in protein-coding sequences, in which case, one of the polymorphic forms may give rise to the expression of a defective or other variant protein. Other single nucleotide polymorphisms occur in noncoding regions. Some of these polymorphisms may also result in defective or variant protein expression (e.g., as a result of defective splicing). Other single nucleotide polymorphisms have no phenotypic effects. Single nucleotide polymorphisms can be used in the same manner as RFLPs, and VNTRs but offer several advantages. Single nucleotide polymorphisms occur with greater frequency and are spaced more uniformly throughout the genome than other forms of polymorphism. The greater frequency and uniformity of single nucleotide polymorphisms means that there is a greater

probability that such a polymorphism will be found in close proximity to a genetic locus of interest than would be the case for other polymorphisms. Also, the different forms of characterized single nucleotide polymorphisms are often easier to distinguish than other types of polymorphism (e.g., by use of assays employing allele-specific hybridization probes or primers).

Despite the increased amount of nucleotide sequence data being generated in recent years, only a minute proportion of the total repository of polymorphisms has so far been identified. The paucity of polymorphisms hitherto identified is due to the large amount of work required for their detection by conventional methods. For example, a conventional approach to identifying polymorphisms might be to sequence the same stretch of oligonucleotides in a population of individuals by didoxy sequencing. In this type of approach, the amount of work increases in proportion to both the length of sequence and the number of individuals in a population and becomes impractical for large stretches of DNA or large numbers of subjects.

SUMMARY OF THE INVENTION

The invention provides nucleic acid segments containing at least 10, 15 or 20 contiguous bases from a fragment shown in Table 1 or 2, the complement thereof, or a plant cognate variant of the fragment. The segments include a polymorphic site shown in Table 1 or 2. The segments can be DNA or RNA, and can be double- or single-stranded. Some segments are 10-20 or 10-50 bases long. Preferred segments include a diallelic polymorphic site.

The invention further provides allele-specific oligonucleotides that hybridizes to a segment of a fragment shown in Table 1 or 2 or its complement. These oligonucleotides can be probes or primers. Also provided are isolated nucleic acids comprising a sequence of Table 1 or 2 or the complement thereto, in which the polymorphic site within the sequence is occupied by a base other than the reference base shown in Table 1 or 2.

The invention further provides a method of analyzing a nucleic acid from a subject. The method determines which base or bases is/are present at any one of the polymorphic sites shown in Table 1 or 2. Optionally, a set of bases occupying a set of the polymorphic sites shown in Table 1 or 2 is determined. This type of analysis can be performed on a plurality of subjects who are tested for the presence of a phenotype. The presence or absence of phenotype can then be correlated with a base or set of bases present at the polymorphic sites in the subjects tested.

BRIEF DESCRIPTION OF THE FIGURE

Fig. 1 shows probe arrays tiles for two allelic forms of the Brassica 18A2 polymorphism.

DEFINITIONS

A nucleic acid, such an oligonucleotide, oligonucleotide can be DNA or RNA, and single- or double-stranded. Oligonucleotides can be naturally occurring or synthetic, but are typically prepared by synthetic means. Preferred nucleic acids of the invention include segments of DNA, or their complements including any one of the polymorphic sites shown in Table 1 or 2. The segments are usually between 5 and 100 bases, and often between 5-10, 5-20, 10-20, 10-50, 20-50 or 20-100 bases. The polymorphic site can occur within any position of the segment. The segments can be from any of the allelic forms of DNA shown in Table 1 or 2. Methods of synthesizing oligonucleotides are found in, for example, *Oligonucleotide Synthesis: A Practical Approach* (Gait, ed., IRL Press, Oxford, 1984).

Hybridization probes are oligonucleotides capable of binding in a base-specific manner to a complementary strand of nucleic acid. Such probes include peptide nucleic acids, as described in Nielsen et al., *Science* 254, 1497-1500 (1991).

The term primer refers to a single-stranded oligonucleotide capable of acting as a point of initiation of template-directed DNA synthesis under appropriate conditions (i.e., in the presence of four different nucleoside

triphosphates and an agent for polymerization, such as, DNA or RNA polymerase or reverse transcriptase) in an appropriate buffer and at a suitable temperature. The appropriate length of a primer depends on the intended use of the primer but typically ranges from 15 to 30 nucleotides. Short primer molecules generally require cooler temperatures to form sufficiently stable hybrid complexes with the template. A primer need not reflect the exact sequence of the template but must be sufficiently complementary to hybridize with a template. The term primer site refers to the area of the target DNA to which a primer hybridizes. The term primer pair means a set of primers including a 5' upstream primer that hybridizes with the 5' end of the DNA sequence to be amplified and a 3', downstream primer that hybridizes with the complement of the 3' end of the sequence to be amplified.

Linkage describes the tendency of genes, alleles, loci or genetic markers to be inherited together as a result of their location on the same chromosome, and can be measured by percent recombination between the two genes, alleles, loci or genetic markers.

Polymorphism refers to the occurrence of two or more genetically determined alternative sequences or alleles in a population. A polymorphic marker or site is the locus at which divergence occurs. Preferred markers have at least two alleles, each occurring at frequency of greater than 1%, and more preferably greater than 10% or 20% of a selected population. A polymorphic locus may be as small as one base pair. Polymorphic markers include restriction fragment length polymorphisms, variable number of tandem repeats (VNTR's), hypervariable regions, minisatellites, dinucleotide repeats, trinucleotide repeats, tetranucleotide repeats, simple sequence repeats, and insertion elements such as Alu. The first identified allelic form is arbitrarily designated as a the reference form and other allelic forms are designated as alternative or variant alleles. The allelic form occurring most frequently in a selected population is sometimes referred to as the wildtype form. Diploid organisms may be homozygous

or heterozygous for allelic forms. A diallelic polymorphism has two forms. A triallelic polymorphism has three forms.

5 A single nucleotide polymorphism occurs at a polymorphic site occupied by a single nucleotide, which is the site of variation between allelic sequences. The site is usually preceded by and followed by highly conserved sequences of the allele (e.g., sequences that vary in less than 1/100 or 1/1000 members of the populations).

10 A single nucleotide polymorphism usually arises due to substitution of one nucleotide for another at the polymorphic site. A transition is the replacement of one purine by another purine or one pyrimidine by another pyrimidine. A transversion is the replacement of a purine by a pyrimidine or vice versa. Single nucleotide polymorphisms can also arise
15 from a deletion of a nucleotide or an insertion of a nucleotide relative to a reference allele.

Hybridizations are usually performed under stringent conditions, for example, at a salt concentration of no more than 1 M and a temperature of at least 25°C. For example,
20 conditions of 5X SSPE (750 mM NaCl, 50 mM NaPhosphate, 5 mM EDTA, pH 7.4) and a temperature of 25-30°C are suitable for allele-specific probe hybridizations.

The invention provides DNA sequences from Brassica and corn and cognate sequences from other plants. The term
25 cognate refers to a gene sequence that is evolutionarily and functionally related between species. Cognate genes typically exhibit a high degree of sequence identity, (e.g., at least 80, 90, 95 or 99%) and hybridize to each other under stringent conditions. A polymorphic site in cognate sequences occur in
30 corresponding positions when the sequences are maximally aligned according to the criteria of any one of the following references: Smith & Waterman (1981), *Adv. Appl. Math.* 2, 482; Needleman & Wunsch (1970), *J. Mol. Biol.* 48: 443; Pearson & Lipman (1988), *Proc. Natl. Acad. Sci. (U.S.A.)* 85: GAP,
35 BESTFIT, FASTA, and TFASTA in the Wisconsin Genetics Software Package, Genetics Computer Group, 575 Science Dr., Madison, WI (each of which is incorporated by reference in its entirety for all purposes).

Nucleic acids of the invention are often in isolated form. An isolated nucleic acid means an object species that is the predominant species present (i.e., on a molar basis it is more abundant than any other individual species in the composition). Preferably, an isolated nucleic acid comprises at least about 50, 80 or 90 percent (on a molar basis) of all macromolecular species present. Most preferably, the object species is purified to essential homogeneity (contaminant species cannot be detected in the composition by conventional detection methods).

DESCRIPTION OF THE PRESENT INVENTION

I. Novel Polymorphisms of the Invention

The present application provides oligonucleotides containing polymorphic sites isolated from two *Brassica* species, *B. napus* and *B. oleracea*, or corn, or cognate sequences from other plants. The invention also includes various methods for using those novel oligonucleotides to identify, distinguish, and determine the relatedness of individual strains or pools of nucleic acids from plants, particularly vegetal plants, and especially plants, within the family *Cruciferae* or *Teosinte*.

The genus *Brassica* is part of the family *Cruciferae*. Members of the *Brassica* genus have been described as Old World Temperate Zone herbs of the mustard family with beaked cylindrical pods. *Merriam-Webster's Collegiate Dictionary*, (10th ed., 1993), p.139. Many cruciferous plants are important agricultural items and include many foodstuffs (condiments, oilseeds, and vegetables). For example, canola (a type of *Brassica napus*) is one of the largest crops in Canada.

Sequences 1-149 in Table 1 and sequences from 86-5B5-N3 to 2B7/2F7-2A in Table 2 were isolated from *B. napus* and *B. oleracea* using oligonucleotide primers designed from expressed DNA sequences from *Arabidopsis thaliana*, a relative of *Brassica napus* and member of the *Cruciferae* family. See Hofte et al., An inventory of expressed sequence tags obtained by partial sequencing of cDNAs from *Arabidopsis thaliana*, Plant

J., Vol.4, pp. 1051-1061 (1993) and Newman et al., Genes Galore: A Summary of Methods for Accessing Results from Large-Scale Partial Sequencing of Anonymous *Arabidopsis* cDNA Clones, *Plant Physiol.*, Vol. 106, pp. 1241-1255 (1994). There is a
5 high degree of homology between the coding sequences of *Arabidopsis*, *Brassica*, and other members of the *Cruciferae* family.

The designations in Table 1 are as follows. The first column is an arbitrarily assigned identification number for a
10 polymorphism. The second and third columns, xmin and ymin, are the co-ordinates of probes for analyzing the polymorphism on a DNA chip (to be described below). The first number in the marker name is the *Brassica* strain name corresponding to the upper allele sequence. The next number designates the
15 primer pair used for the PCR amplification. The sequences of some primers are described at the web site (http://www.yorku.ca/ftp/york_other/cgat/) (incorporated by reference in its entirety for all purposes). The last number is the name of the strain for the lower allele sequence. For
20 example 85/5B5/86-1 means that the polymorphic site was identified by comparing strains 85 and 86-1 at a segment amplified by primers 5B5. Each sequence in the table includes a polymorphic site shown in square brackets [] and flanking bases common to both strains being compared. The upper and
25 lower sequences in the square brackets are from the two strains being compared (upper strand corresponding to the first designated strain). A "/" within square brackets followed or preceded by a blank space represents an addition/deletion polymorphism. An asterisk indicates
30 triallelic markers. The designation N indicates a base whose identity was not determined. The nomenclature for Table 2 is similar except that only fragment names and sequences flanking and including polymorphic sites are shown. In both Tables 1 and 2, the symbol "T" should be read as a "U" in RNA forms of
35 the nucleic acids provided by the invention.

The invention further provides oligonucleotides from corn (*zea maize*), and cognate sequences from other plants especially those from the *Teosinte* family in which corn falls.

DNA was extracted from maize lines as described in Rogers and Bendich, *Plant Biol. Manual* A6, 1-10 (1988) with modification described in Murigneux et al., *Theo. Appl. Genet.* 86, 837-842 (1993). PCR amplification was done on six maize lines

5 representing a wide range of genetic variability and including both European flint material and US dent germplasm. These six maize lines were chosen to maximize genetic variability and thereby improve the probability of finding polymorphisms in the allelic sequences. Preferred primers for amplification
10 of some DNA segments including polymorphic sites are shown in Table 3. Other primers can be designed to incorporate sequences flanking the nucleic acid segments listed in Tables 1 and 2. Flanking sequences can be obtained from GenBank, or Bae et al., *Maydica* 35, 317-322 (1990), or PCR-based gene
15 walking. See Parker et al., *Nucl. Acids Res.* 19, 3055-3060. A specific primer for the sequenced region is primed with a general primer that hybridizes to the flanking region.

Nucleic acid segments flanking polymorphic sites in Zea Maize are shown as sequences 150-264 of Table 1, and sequences
20 from S71G2/G6-1 to S01G3/G7-2 in Table 2. The nomenclature is the same as that described earlier for *Brassica* sequences.

II. Analysis of Polymorphisms

A. Preparation of Samples

25 Polymorphisms are detected in a target nucleic acid from a plant being analyzed. Target nucleic acids can be genomic or cDNA. Many of the methods described below require amplification of DNA from target samples. This can be accomplished by e.g., PCR. See generally *PCR Technology: Principles and Applications for DNA Amplification* (ed. H.A. Erlich, Freeman Press, NY, NY, 1992); *PCR Protocols: A Guide to Methods and Applications* (eds. Innis, et al., Academic Press, San Diego, CA, 1990); Mattila et al., *Nucleic Acids Res.* 19, 4967 (1991); Eckert et al., *PCR Methods and*
30 *Applications* 1, 17 (1991); PCR (eds. McPherson et al., IRL Press, Oxford); and U.S. Patent 4,683,202 (each of which is incorporated by reference for all purposes).

Other suitable amplification methods include the ligase chain reaction (LCR) (see Wu and Wallace, *Genomics* 4, 560 (1989), Landegren et al., *Science* 241, 1077 (1988), transcription amplification (Kwoh et al., *Proc. Natl. Acad. Sci. USA* 86, 1173 (1989)), and self-sustained sequence replication (Guatelli et al., *Proc. Nat. Acad. Sci. USA*, 87, 1874 (1990)) and nucleic acid based sequence amplification (NASBA). The latter two amplification methods involve isothermal reactions based on isothermal transcription, which produce both single stranded RNA (ssRNA) and double stranded DNA (dsDNA) as the amplification products in a ratio of about 30 or 100 to 1, respectively.

B. Detection of Polymorphisms in Target DNA

There are two distinct types of analysis depending whether a polymorphism in question has already been characterized. The first type of analysis is sometimes referred to as de novo characterization. This analysis compares target sequences in different individual plants to identify points of variation, i.e., polymorphic sites. The de novo identification of the polymorphisms of the invention is described in the Examples section. The second type of analysis is determining which form(s) of a characterized polymorphism are present in plants under test. There are a variety of suitable procedures, which are discussed in turn.

1. Allele-Specific Probes

The design and use of allele-specific probes for analyzing polymorphisms is described by e.g., Saiki et al., *Nature* 324, 163-166 (1986); Dattagupta, EP 235,726, Saiki, WO 89/11548. Allele-specific probes can be designed that hybridize to a segment of target DNA from one member of a species but do not hybridize to the corresponding segment from another member due to the presence of different polymorphic forms in the respective segments from the two members. Hybridization conditions should be sufficiently stringent that there is a significant difference in hybridization intensity between alleles, and preferably an essentially binary

response, whereby a probe hybridizes to only one of the alleles. Some probes are designed to hybridize to a segment of target DNA such that the polymorphic site aligns with a central position (e.g., in a 15 mer at the 7 position; in a 16
5 mer, at either the 8 or 9 position) of the probe. This design of probe achieves good discrimination in hybridization between different allelic forms.

Allele-specific probes are often used in pairs, one member of a pair showing a perfect match to a reference form
10 of a target sequence and the other member showing a perfect match to a variant form. Several pairs of probes can then be immobilized on the same support for simultaneous analysis of multiple polymorphisms within the same target sequence.

15 2. Tiling Arrays

The polymorphisms can also be identified by hybridization to nucleic acid arrays, some example of which are described by WO 95/11995 (incorporated by reference in its entirety for all purposes). One form of such arrays is
20 described in the Examples section in connection with de novo identification of polymorphisms. The same array or a different array can be used for analysis of characterized polymorphisms. WO 95/11995 also describes subarrays that are optimized for detection of a variant forms of a
25 precharacterized polymorphism. Such a subarray contains probes designed to be complementary to a second reference sequence, which is an allelic variant of the first reference sequence. The second group of probes is designed by the same principles as described in the Examples except that the probes
30 exhibit complementarity to the second reference sequence. The inclusion of a second group (or further groups) can be particularly useful for analyzing short subsequences of the primary reference sequence in which multiple mutations are expected to occur within a short distance commensurate with
35 the length of the probes (i.e., two or more mutations within 9 to 21 bases).

A DNA chip has been designed containing subarrays of probes for analyzing each of the 264 polymorphic sites shown

in Table 1. Preferred polymorphic sites for inclusion on such a chip are selected by a number of criteria. Some polymorphic sites are selected because they are evenly distributed throughout the genome of a plant. For example, one or more polymorphisms is present on each chromosome. Preferably, the polymorphisms are no more than 20 cM apart. Other polymorphisms are selected because they occur within a segment that can be made to give a single band on Southern analysis. Other polymorphisms may be selected because they occur in genes encoding enzymes that function in the same pathway.

Preferred primer pairs for amplification of nucleic acid segments flanking most of these polymorphic sites of Table 1 are shown in Table 3. This chip is used to determine a polymorphic profile of a plant under test at some or all of the polymorphic sites on the chip. Thus, one can determine which allelic form is present in a plant at up to 264 sites. Such a profile is useful in some of the applications described below.

DNA segments are preferably amplified in a multiplex fashion. For example, polymorphic sites 5, 8, 64, 108, 36, 38, and 136 (Table 1) can be amplified from the primers shown in Table 3 in one group. Polymorphic sites 11, 12, 15, 29, 130, 139, 140, 40, 49, 63, 72, 81, 86, 92, 93, 102, 142, 146, 149, 16, 138 can be amplified in another group. Polymorphic sites 1, 7, 17, 25, 26, 42, 60, 67, 73, 75, 106, 107, 111, 123, 133, 43, 51, 82, 95, and 101 can be amplified in another group. Polymorphic sites 2, 9, 20, 34, 41, 45, 61, 62, 65, 74, 75, 80, 91, 100, 105, 110, 123, and 14 can be amplified in another group. Polymorphic sites 4, 41, 61, 62, 65, 66, 76, 80, 91, 94, 111, 114, 121, 132, 22, 32, 33, 44, 53, 97 and 145 can be amplified in another group. Polymorphic sites 6, 21, 27, 46, 66, 68, 71, 77, 89, 89, 98, 103, 105, 31, 35, 54, 59, 84, 85, 96, 116, 137, 141, and 148 can be amplified in another group. Polymorphic sites 48, 70, 78, 87, 88, 90, 99, 103, 104, 112, 117, 118, 119, 122, 124, 13, 18, 30, 37, 69, 94, 135, and 147 can be amplified in another group. Polymorphic sites 247, 207, 203, and 173 can be amplified in another group. Polymorphic sites 229, 217, 212, 204, 195, 171, 175,

236, 174, and 193 can be amplified in another group.

Polymorphic sites 232, 243, 157, 162, 169, 177, 179, 234, 241, 255, 152, 160, 184, 188, 192, 199, 201, 205, 210, 220, 223, 226, 245, 249, and 252 can be amplified in another group.

5 Polymorphic sites 233, 244, 246, 248, 227, 211, 214, 200, 150, 158, 170, 178, 181, 238, 254, 161, 165, 180, 187, 222, and 231 can be amplified from another group. Polymorphic sites 228, 235, 215, 218, 221, 225, 198, 155, 163, 166, 167, 172, 216, 242, 159, 182, 186, 191, 202, 208, 230, 237, and 253 can be
10 amplified in another group. Polymorphic sites 219, 224, 206, 209, 213, 194, 196, 197, 151, 153, 156, 164, 185, 250, 154, 168, 176, 183, 190, 239, 251, and 256 can be amplified in another group.

15 3. Allele-Specific Primers

An allele-specific primer hybridizes to a site on target DNA overlapping a polymorphism and only primes amplification of an allelic form to which the primer exhibits perfect complementarity. See Gibbs, *Nucleic Acid Res.* 17, 2427-2448 (1989). This primer is used in conjunction with a
20 second primer which hybridizes at a distal site. Amplification proceeds from the two primers leading to a detectable product signifying the particular allelic form is present. A control is usually performed with a second pair of
25 primers, one of which shows a single base mismatch at the polymorphic site and the other of which exhibits perfect complementarity to a distal site. The single-base mismatch prevents amplification and no detectable product is formed. The method works best when the mismatch is included in the 3'-
30 most position of the oligonucleotide aligned with the polymorphism because this position is most destabilizing to elongation from the primer. See, e.g., WO 93/22456.

4. Direct-Sequencing

35 The direct analysis of the sequence of polymorphisms of the present invention can be accomplished using either the dideoxy chain termination method or the Maxam Gilbert method (see Sambrook et al., *Molecular Cloning*, A

Laboratory Manual (2nd Ed., CSHP, New York 1989); Zyskind et al., *Recombinant DNA Laboratory Manual*, (Acad. Press, 1988)).

5 5. Denaturing Gradient Gel Electrophoresis

 Amplification products generated using the polymerase chain reaction can be analyzed by the use of denaturing gradient gel electrophoresis. Different alleles can be identified based on the different sequence-dependent melting properties and electrophoretic migration of DNA in solution. Erlich, ed., *PCR Technology, Principles and Applications for DNA Amplification*, (W.H. Freeman and Co, New York, 1992), Chapter 7.

15 6. Single-Strand Conformation Polymorphism Analysis

 Alleles of target sequences can be differentiated using single-strand conformation polymorphism analysis, which identifies base differences by alteration in electrophoretic migration of single stranded PCR products, as described in Orita et al., *Proc. Nat. Acad. Sci.* 86, 2766-2770 (1989). Amplified PCR products can be generated as described above, and heated or otherwise denatured, to form single stranded amplification products. Single-stranded nucleic acids may refold or form secondary structures which are partially dependent on the base sequence. The different electrophoretic mobilities of single-stranded amplification products can be related to base-sequence difference between alleles of target sequences.

30 III. Methods of Use

 After determining polymorphic form(s) present in a subject plant at one or more polymorphic sites, this information can be used in a number of methods.

 A. Fingerprint Analysis

35 Analysis of which polymorphisms are present in a plant is useful in determining of which strain the plant is a member in distinguishing one strain from another. A genetic fingerprint for an individual strain can be made by determining the nucleic acid sequence possessed by that

individual strain that corresponds to a region of the genome known to contain polymorphisms. For a discussion of genetic fingerprinting in the animal kingdom, see, for example, Stokening et.al., *Am. J. Hum. Genet.* 48:370-382 (1991). The probability that one or more polymorphisms in an individual strain is the same as that in any other individual strain decreases as the number of polymorphic sites is increased.

The comparison of the nucleic acid sequences from two strains at one or multiple polymorphic sites can also demonstrate common or disparate ancestry. Since the polymorphic sites are within a large region in the genome, the probability of recombination between these polymorphic sites is low. That low probability means the haplotype (the set of all the disclosed polymorphic sites) set forth in this application should be inherited without change for at least several generations. Knowledge of plant strain or ancestry is useful, for example, in a plant breeding program or in tracing progeny of a proprietary plant. Fingerprints are also used to identify an individual strain and to distinguish or determine the relatedness of one individual strain to another. Genetic fingerprinting can also be useful in hybrid certification, the certification of seed lots, and the assertion of plant breeders rights under the laws of various countries.

Genetic fingerprinting is also useful in screening progeny of a backcross for a high contribution of a parent strain (see Hospital et al., *Genetics* 44, 843-874 (1992)). In a backcross, a progeny that has been bred to have a desired phenotype is crossed with a parental strain to remove genetic variations that do not contribute to the desired phenotype but which may have latent undesirable effects. After crossing, offspring retaining the desired phenotype are identified, and their polymorphic profile is determined. The offspring retaining the desired phenotype and having the greatest similarity in polymorphic profile to a parent strain can then be used as a production model.

B. Correlation of Polymorphisms with Phenotypic Traits

The polymorphisms of the invention may contribute to the phenotype of a plant in different ways. Some polymorphisms occur within a protein coding sequence and
5 contribute to phenotype by affecting protein structure. The effect may be neutral, beneficial or detrimental, or both beneficial and detrimental, depending on the circumstances. Other polymorphisms occur in noncoding regions but may exert phenotypic effects indirectly via influence on replication,
10 transcription, and translation. A single polymorphism may affect more than one phenotypic trait. Likewise, a single phenotypic trait may be affected by polymorphisms in different genes. Further, some polymorphisms predispose a plant to a distinct mutation that is causally related to a certain
15 phenotype.

Phenotypic traits include characteristics such as growth rate, crop yield, crop quality, resistance to pathogens, herbicides, and other toxins, nutrient requirements, resistance to high temperature, freezing,
20 drought, requirements for light and soil type, aesthetics, and height. Other phenotypic traits include susceptibility or resistance to diseases, such as plant cancers. Often polymorphisms occurring within the same gene correlate with the same phenotype.

25 Correlation is performed for a population of plants, which have been tested for the presence or absence of a phenotypic trait of interest and for polymorphic markers sets. To perform such analysis, the presence or absence of a set of polymorphisms (i.e. a polymorphic set) is determined for a set
30 of the plants, some of whom exhibit a particular trait, and some of which exhibit lack of the trait. The alleles of each polymorphism of the set are then reviewed to determine whether the presence or absence of a particular allele is associated with the trait of interest. Correlation can be performed by
35 standard statistical methods such as a χ -squared test and statistically significant correlations between polymorphic form(s) and phenotypic characteristics are noted.

Correlations between characteristics and phenotype are useful for breeding for desired characteristics. By analogy, Beitz et al., US 5,292,639 discuss use of bovine mitochondrial polymorphisms in a breeding program to improve milk production in cows. To evaluate the effect of mtDNA D-loop sequence polymorphism on milk production, each cow was assigned a value of 1 if variant or 0 if wildtype with respect to a prototypical mitochondrial DNA sequence at each of 17 locations considered. Each production trait was analyzed individually with the following animal model:

$$Y_{ijkpn} = \mu + YS_i + P_j + X_k + \beta_1 + \dots \beta_{17} + PE_n + a_n + e_p$$

where Y_{ijkpn} is the milk, fat, fat percentage, SNF, SNF percentage, energy concentration, or lactation energy record; μ is an overall mean; YS_i is the effect common to all cows calving in year-season; X_k is the effect common to cows in either the high or average selection line; β_1 to β_{17} are the binomial regressions of production record on mtDNA D-loop sequence polymorphisms; PE_n is permanent environmental effect common to all records of cow n ; a_n is effect of animal n and is composed of the additive genetic contribution of sire and dam breeding values and a Mendelian sampling effect; and e_p is a random residual. It was found that eleven of seventeen polymorphisms tested influenced at least one production trait. Bovines having the best polymorphic forms for milk production at these eleven loci are used as parents for breeding the next generation of the herd.

One can test at least several hundreds of markers simultaneously in order to identify those linked to a gene or chromosomal region. For example, to identify markers linked to a gene conferring disease resistance, a DNA pool is constructed from plants of a segregating population that are resistant and another pool is constructed from plants that are sensitive to the disease. Those two DNA pools are identical except for the DNA sequences at the resistance gene locus and in the surrounding genomic area. Hybridization of such DNA pools to the DNA sequences listed in Table 1 allows the simultaneous testing of several hundreds of loci for polymorphisms. Allelic polymorphism-detecting sequences that

show differences in hybridization patterns between such DNA pools represent loci linked to the disease resistance gene.

The method just described can also be applied to rapidly identify rare alleles in large populations of plants.

5 For example, nucleic acid pools are constructed from several individuals of a large population. The nucleic acid pools are hybridized to nucleic acids having the polymorphism-detecting sequences listed in Table 1 or 2. The detection of a rare hybridization profile will indicate the presence of a rare
10 allele in a specific nucleic acid pool. RNA pools are particularly suited to identify differences in gene expression.

IV. Modified Polypeptides and Gene Sequences

15 The invention further provides variant forms of nucleic acids and corresponding proteins. The nucleic acids comprise at least 10 contiguous bases of one of the sequences described in Table 1 or 2, in any of the allelic forms shown. Some nucleic acid encode full-length proteins.

20 Genes can be expressed in an expression vector in which a gene is operably linked to a native or other promoter. Usually, the promoter is a eukaryotic promoter for expression in a eukaryotic cell. The transcription regulation sequences typically include a heterologous promoter and optionally an
25 enhancer which is recognized by the host. The selection of an appropriate promoter, for example trp, lac, phage promoters, glycolytic enzyme promoters and tRNA promoters, depends on the host selected. Commercially available expression vectors can be used. Vectors can include host-recognized replication
30 systems, amplifiable genes, selectable markers, host sequences useful for insertion into the host genome, and the like.

The means of introducing the expression construct into a host cell varies depending upon the particular construction and the target host. Suitable means include fusion,
35 conjugation, transfection, transduction, electroporation or injection, as described in Sambrook, *supra*. A wide variety of host cells can be employed for expression of the variant gene, both prokaryotic and eukaryotic. Suitable host cells include

bacteria such as *E. coli*, yeast, filamentous fungi, insect cells, mammalian cells, typically immortalized, e.g., mouse, CHO, human and monkey cell lines and derivatives thereof, and plant cells. Preferred host cells are able to process the variant gene product to produce an appropriate mature polypeptide. Processing includes glycosylation, ubiquitination, disulfide bond formation, general post-translational modification, and the like.

The DNA fragments are introduced into cultured plant cells by standard methods including electroporation (From et al., *Proc. Natl Acad. Sci. USA* 82, 5824 (1985), infection by viral vectors such as cauliflower mosaic virus (CaMV) (Hohn et al., *Molecular Biology of Plant Tumors*, (Academic Press, New York, 1982) pp. 549-560; Howell, US 4,407,956), high velocity ballistic penetration by small particles with the nucleic acid either within the matrix of small beads or particles, or on the surface (Klein et al., *Nature* 327, 70-73 (1987)), use of pollen as vector (WO 85/01856), or use of *Agrobacterium tumefaciens* transformed with a Ti plasmid in which DNA fragments are cloned. The Ti plasmid is transmitted to plant cells upon infection by *Agrobacterium tumefaciens*, and is stably integrated into the plant genome (Horsch et al., *Science*, 233, 496-498 (1984); Fraley et al., *Proc. Natl. Acad. Sci. USA* 80, 4803 (1983)).

The protein may be isolated by conventional means of protein biochemistry and purification to obtain a substantially pure product, i.e., 80, 95 or 99% free of cell component contaminants, as described in Jacoby, *Methods in Enzymology* Volume 104, Academic Press, New York (1984); Scopes, *Protein Purification, Principles and Practice*, 2nd Edition, Springer-Verlag, New York (1987); and Deutscher (ed), *Guide to Protein Purification, Methods in Enzymology*, Vol. 182 (1990). If the protein is secreted, it can be isolated from the supernatant in which the host cell is grown. If not secreted, the protein can be isolated from a lysate of the host cells.

The invention further provides transgenic plants capable of expressing an exogenous variant gene and/or having

one or both alleles of an endogenous variant gene inactivated. Plant regeneration from cultural protoplasts is described in Evans et al., "Protoplasts Isolation and Culture," *Handbook of Plant Cell Cultures* 1, 124-176 (MacMillan Publishing Co., New York, 1983); Davey, "Recent Developments in the Culture and Regeneration of Plant Protoplasts," *Protoplasts*, (1983) - pp. 12-29, (Birkhauser, Basel 1983); Dale, "Protoplast Culture and Plant Regeneration of Cereals and Other Recalcitrant Crops," *Protoplasts* (1983) - pp. 31-41, (Birkhauser, Basel 1983); Binding, "Regeneration of Plants," *Plant Protoplasts*, pp. 21-73, (CRC Press, Boca Raton, 1985). For example, a variant gene responsible for a disease-resistant phenotype can be introduced into the plant to simulate that phenotype. Expression of an exogenous variant gene is usually achieved by operably linking the gene to a promoter and optionally an enhancer. Inactivation of endogenous variant genes can be achieved by forming a transgene in which a cloned variant gene is inactivated by insertion of a positive selection marker. See Capecchi, *Science* 244, 1288-1292 (1989). Such transgenic plants are useful in a variety of screening assays. For example, the transgenic plant can then be treated with compounds of interest and the effect of those compounds on the disease resistance can be monitored. In another example, the transgenic plant can be exposed to a variety of environmental conditions to determine the effect of those conditions on the resistance to the disease.

In addition to substantially full-length polypeptides, the present invention includes biologically active fragments of the polypeptides, or analogs thereof, including organic molecules which simulate the interactions of the peptides. Biologically active fragments include any portion of the full-length polypeptide which confers a biological function on the variant gene product, including ligand binding, and antibody binding. Ligand binding includes binding by nucleic acids, proteins or polypeptides, small biologically active molecules, or large cellular structures.

Polyclonal and/or monoclonal antibodies that specifically bind to one allelic gene products but not to a

second allelic gene product are also provided. Antibodies can be made by injecting mice or other animals with the variant gene product or synthetic peptide fragments thereof.

Monoclonal antibodies are screened as are described, for

5 example, in Harlow & Lane, *Antibodies, A Laboratory Manual*, Cold Spring Harbor Press, New York (1988); Goding, *Monoclonal antibodies, Principles and Practice* (2d ed.) Academic Press, New York (1986). Monoclonal antibodies are tested for
10 specific immunoreactivity with a variant gene product and lack of immunoreactivity to the corresponding prototypical gene product. These antibodies are useful in diagnostic assays for detection of the variant form, or as an active ingredient in a pharmaceutical composition.

15 V. Kits

The invention further provides kits comprising at least one allele-specific oligonucleotide as described above. Often, the kits contain one or more pairs of allele-specific oligonucleotides hybridizing to different forms of a
20 polymorphism. In some kits, the allele-specific oligonucleotides are provided immobilized to a substrate. For example, the same substrate can comprise allele-specific oligonucleotide probes for detecting at least 10, 100 or all of the polymorphisms shown in Table 1 or 2. Optional
25 additional components of the kit include, for example, restriction enzymes, reverse-transcriptase or polymerase, the substrate nucleoside triphosphates, means used to label (for example, an avidin-enzyme conjugate and enzyme substrate and chromogen if the label is biotin), and the appropriate buffers
30 for reverse transcription, PCR, or hybridization reactions. Usually, the kit also contains instructions for carrying out the methods.

EXAMPLES

35 As noted above, the sequences in Table 1 were isolated from *B. napus* and *B. oleracea* using oligonucleotide primers designed from expressed DNA sequences from *Arabidopsis thaliana*, a relative of *Brassica napus* and member of the

Cruciferae family. Primers used to amplify *B. napus* and *B. oleracea* alleles were selected for an optimal length of 20 bases \pm 2 based such that their melting temperatures were between 60°C and 65°C. Primers were synthesized on a 20 nmole scale using a high throughput DNA synthesizer capable of producing 96 primers simultaneously in a 96-well format. See Lashkari et al., *Proc. Nat. Acad. Sci.* 92, 7912-7915 (1995). The primers, which have an average length of 21 bases, were positioned within DNA sequences such that PCR products produced with cDNA templates would range between 100 and 450 bp. As introns in *Arabidopsis* genes are of modest size, 60% of the 1,920 primers tested on plant DNA gave PCR products.

The components needed for PCR amplification were mixed in the following proportions for a 96 well microamp tray assembly: 206:1 of 10X PCR reaction buffer, 206:1 of 2 mM dNTPs, 186:1 of 15 mM MgCl₂, 720:1 of sterile ddH₂O and, 20:1 of Taq DNA polymerase (Perkin Elmer). The enzyme was added just prior to dispensing 168:1 of this master mix into 8 tubes. 20:1 of the appropriate forward and reverse primer 10 pmol/l stock solutions was added to each tube. A volume of 14:1 of this mixture was dispensed into each well of the microamp assembly with a BioHit 8-channel pipette. A volume of 5:1 of 20 ng/l template DNA solutions was added to the microamp assembly with a 12-channel pipette. The assembly was centrifuged for 30 sec to ensure that all reagents were mixed. Amplifications were performed in a Perkin Elmer system 9600 thermal cycler with an initial denaturation at 95°C for 1 min followed by 40 cycles of 94°C for 30 sec, 55°C for 30 sec, 72°C for 30 sec and a final extension at 72°C for 5 min. Products were separated by electrophoresis at 120 volts for 1 hr through 2% (w/v) agarose gels prestained with ethidium bromide. The banding patterns of these gels were recorded with an Alpha Innotech gel documentation system.

Any two amplicons obtained from the same primer set with two different plant varieties are said to be homomorphic if they have the same size. A set of 355 homomorphic *Brassica napus* and 250 homomorphic *Brassica oleracea* fragments were purified with Quiaquick columns and sequenced using dye

labeled dideoxy-terminators. See Stryer, *Biochemistry* 2nd. ed., pp. 592-593 (1981). The same primers used for the PCR amplification of the homomorphic DNA fragments were also used for the DNA sequencing of these fragments. The sequences
5 obtained were aligned to identify single nucleotide polymorphisms.

Using VLSIPSTM technology (US 5,143,854; WO 90/15070; WO 92/10092), GeneChipJ was constructed using 20mer-probe sets to identify by hybridization the presence or absence of many
10 of the polymorphisms shown in Table 1 in a sample of plant nucleic acid. The tiling strategy used to create the GeneChipJ is set forth in Figure 1. Tiling strategies can be devised using the guidance provided herein by those skilled in the art. Tiling arrays are described in PCT/US94/12305
15 (incorporated by reference in its entirety for all purposes). ATiling@ generally means the synthesis of a defined set of oligonucleotide probes that is made up of a sequence complementary to the sequence to be analyzed (the target sequence), as well as preselected variations of that sequence.
20 The variations usually include substitution at one or more base positions with one or more nucleotides. Tiling strategies are discussed in Published PCT Application No. WO 95/11995 (incorporated by reference in its entirety for all purposes). In general, with a tiled array containing 4L
25 probes one can query every position in a nucleotide containing L number of bases. A 4L tiled array, for example, contains L number of sets of 4 probes, i.e. 4L probes. Each set of 4 probes contains the perfect complement to a portion of the target sequence with a single substitution for each nucleotide
30 at the same position in the probe. See also Chee, M., et. al., *Science*, October, 1996.

The tiling strategy for 20mer probes shown in Figure 1 for a single allele of the polymorphism employed probe sets having a perfect match and a corresponding single-base
35 mismatch at the tenth base in the probe, counting from the 3= end. Each set had 14 pairs of probes that began at 14 successively shifted positions such that the substituted base lay from 7 bases upstream to 6 bases downstream from the

polymorphic site. Two such sets of 28 probes were included to query the polymorphic site for the two alleles, as shown for example, in Figure 1. This collection of 56 probes constituted a detection block. Two such blocks per marker were synthesized to query both the forward and reverse strands. Thus each marker interrogated by the GeneChipJ was represented by a full set of 112 probes.

All publications and patent applications cited above are incorporated by reference in their entirety for all purposes to the same extent as if each individual publication or patent application were specifically and individually indicated to be so incorporated by reference. Although the present invention has been described in some detail by way of illustration and example for purposes of clarity and understanding, it will be apparent that certain changes and modifications may be practiced within the scope of the appended claims.

WHAT IS CLAIMED IS:

1. A nucleic acid segment comprising at least 10
contiguous nucleotides including a polymorphic site from a
5 sequence shown in Table 1 or Table 2, or a plant cognate
variant thereof, or the complement of the segment.

2. The nucleic acid segment of claim 1, wherein the
segment is less than 100 bases.

3. The segment of claim 1 that is less than 50 bases.

4. The segment of claim 1 that is less than 20
bases.

5. The nucleic acid segment of claim 1, wherein the
segment contains at least 10 contiguous nucleotides including
a polymorphic site from a sequence shown in Table 1.

6. The nucleic acid segment of claim 5, wherein the
sequence is a Brassica sequence.

7. The nucleic acid segment of claim 5, wherein the
sequence is a corn sequence.

8. The nucleic acid segment of claim 1 that is DNA.

9. The nucleic acid segment of claim 1 that is RNA.

10. The segment of claim 1, wherein the polymorphic
site is diallelic.

11. An allele-specific oligonucleotide that
hybridizes to a sequence shown in Table 1 or 2, or its
35 complement.

12. The allele-specific oligonucleotide of claim 11
that is a probe.

13. The allele-specific oligonucleotide of claim 11, wherein the a central position of the probe aligns with the polymorphic site in the sequence.

5 14. The allele-specific oligonucleotide of claim 11 that is a primer.

10 15. The allele-specific oligonucleotide of claim 11, wherein the 3' end of the primer aligns with the polymorphic site of the segment.

15 16. A method of analyzing a nucleic acid, comprising: obtaining the nucleic acid from a plant, and determining a base occupying any one of the polymorphic sites shown in Table 1 or 2.

20 17. The method of claim 16, wherein the determining comprises determining a set of bases occupying a set of the polymorphic sites shown in Table 1.

25 18. The method of claim 17, wherein the nucleic acid is obtained from a plurality of plants, and a base occupying one of the polymorphic positions is determined in each of the subjects, and the method further comprises testing each plant for the presence of a phenotype, and correlating the presence of the phenotype with the base.

30 19. Use of a polymorphism shown in Table 1 or 2, a nucleic acid segment of claim 1, or an allele-specific oligonucleotide of claim 11 to determine common or disparate ancestry between two or more plants.

35 20. Use of a polymorphism shown in Table 1 or 2, a nucleic acid segment of claim 1, or an allele-specific oligonucleotide of claim 11 in plant breeding.

21. Use according to claim 20, wherein the polymorphism, nucleic acid segment or allele-specific

oligonucleotide is used to monitor a genetic contribution of an ancestral plant to a progeny plant.

5 22. Use of a polymorphism shown in Table 1 or 2, a nucleic acid segment of claim 1, or an allele-specific oligonucleotide of claim 11 to trace progeny of a proprietary plant.

10 23. Use of a polymorphism shown in Table 1 or 2, a nucleic acid segment of claim 1, or an allele-specific oligonucleotide of claim 11 in certification of a hybrid plant.

15 24. Use of a polymorphism shown in Table 1 or 2, a nucleic acid segment of claim 1, or an allele-specific oligonucleotide of claim 11 to identify a progeny of a backcross of a selected plant with an ancestral plant having a desired genetic contribution from the ancestral plant.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US97/21782

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) : C07H 21/00, 21/02, 21/04; C12N 15/09; C12Q 1/68

US CL : 435/6, 172.3; 536/23.1, 24.3

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 435/6, 172.3; 536/23.1, 24.3

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

Databases: APS, Medline, Biosis, Genbank

Search Terms: Brassica; polymorph?; restriction; fragment?; length; rflp; lemieux?/au; landry?/au; sapolsky?/au

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	CROSS et al. Purification of CpG islands using methylated DNA binding column. Nature Genetics. March 1994, Vol. 6, pages 236-244, see entire document, especially sequences.	1-24

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US97/21782

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Extra Sheet.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
1-24 (in part)

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

PCT/US97/21782

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

This application contains claims directed to more than one species of the generic invention. These species are deemed to lack Unity of Invention because they are not so linked as to form a single inventive concept under PCT Rule 13.1. The species are as follows:

Each of the 1282 sequences listed in Tables 1-3 are a separate species because there is no requisite structural relationship between the species. Therefore, the species cited above do not relate to a single inventive concept under PCT Rule 13.1 because under PCT Rule 13.2, the species lack the same or corresponding special technical feature. There is no structural relationship between the separately recited sequences.

Applicant is entitled to have ten (10) specified sequences searched and no more than four (4) additional sequences search for each additional fee. Since no fee has been paid, the first ten (10) sequences listed in Table 1 have been searched.
